Analog control

[Analog Read Serial | Arduino Documentation | Arduino Documentation](#)

```
void setup() {
  // initialize serial communication at 9600 bits per second:
  Serial.begin(9600);
}

// the setup routine runs once when you press reset:
void setup() {
  // initialize serial communication at 9600 bits per second:
  Serial.begin(9600);
}

// the loop routine runs over and over again forever:
void loop() {
  // read the input on analog pin 0:
  int sensorValue = analogRead(A0);
  // map it to the range of the potentiometer:
  int outputValue = map(sensorValue, 0, 1023, 0, 255);
  // change the analog output value:
  analogWrite(analogOutPin, outputValue);
  // print the results to the Serial Monitor:
  Serial.print("Sensor = ");
  Serial.print(sensorValue);
  Serial.print("\t");
  Serial.print("output = ");
  Serial.print(outputValue);
  // wait 2 milliseconds before the next loop for the analog-to-digital
  // converter to settle after the last reading:
  delay(2);
}
```

LED Dimming Example

Uses PWM signals

/*

Analog input, analog output, serial output

Reads an analog input pin, maps the result to a range from 0 to 255 and uses

the result to set the pulse width modulation (PWM) of an output pin.

Also prints the results to the Serial Monitor.

The circuit:

- potentiometer connected to analog pin 0.

Center pin of the potentiometer goes to the analog pin.

side pins of the potentiometer go to +5V and ground

- LED connected from digital pin 9 to ground

This example code is in the public domain.

<http://www.arduino.cc/tutorials/www.arduino.cc/en/Tutorial/AnalogOutSerial>

*/

```
/*
 * These constants won't change. They're used to give names to the pins used:
 */
const int analogInPin = A0; // Analog input pin that the potentiometer is attached to
const int analogOutPin = 9; // Analog output pin that the LED is attached to

int sensorValue = 0; // value read from the pot
int outputValue = 0; // value output to the PWM (analog out)

void setup() {
  // initialize serial communications at 9600 bps:
  Serial.begin(9600);
}

void loop() {
  // read the analog in value:
  sensorValue = analogRead(analogInPin);
  // map it to the range of the analog out:
  outputValue = map(sensorValue, 0, 1023, 0, 255);
  // change the analog out value:
  analogWrite(analogOutPin, outputValue);
  // print the results to the Serial Monitor:
  Serial.print("Sensor = ");
  Serial.print(sensorValue);
  Serial.print("\t");
  Serial.print("output = ");
  Serial.print(outputValue);
  // wait 2 milliseconds before the next loop for the analog-to-digital
  // converter to settle after the last reading:
  delay(2);
}
```

Digital Control

[How to Wire and Program a Button | Arduino Documentation | Arduino Documentation](#)

```
void setup() {
  // initialize the pushbutton pin as an input:
  pinMode(buttonPin, INPUT);
}

// variables for reading the pushbutton status
int ledState = HIGH; // the current state of the pushbutton
int buttonState = LOW; // the previous reading from the input pin

// the following variables are unsigned longs because the time, measured in
// milliseconds, will quickly become a bigger number than can be stored in an int.
unsigned long lastDebounceTime = 0; // the last time the output pin was toggled
unsigned long debounceDelay = 50; // the debounce time; increase if the output flickers

void setup() {
  pinMode(buttonPin, INPUT);
  pinMode(ledPin, OUTPUT);
  // set initial LED state
  digitalWrite(ledPin, ledState);
}

void loop() {
  // read the state of the switch into a local variable:
  int reading = digitalRead(buttonPin);
  // check to see if you just pressed the button
  // (i.e. the input went from LOW to HIGH), and you've waited long enough
  // since the last press to ignore any noise:
  // If the switch changed, due to noise or pressing:
  if (reading != lastButtonState) {
    // reset the debouncing timer
    lastDebounceTime = millis();
  }
  if ((millis() - lastDebounceTime) > debounceDelay) {
    // whatever the reading is at, it's been there for longer than the debounce
    // delay, so take it as the actual current state:
    // If the button state has changed:
    if (reading != buttonState) {
      buttonState = reading;
      // only toggle the LED if the new button state is HIGH
      if (buttonState == HIGH) {
        ledState = !ledState;
      }
    }
    // set the LED:
    digitalWrite(ledPin, ledState);
    // save the reading. Next time through the loop, it'll be the lastButtonState:
    lastButtonState = reading;
  }
}
```

Switch debouncing

[Debounce on a Pushbutton | Arduino Documentation | Arduino Documentation](#)

/*

Debounce

Each time the input pin goes from LOW to HIGH (e.g. because of a push-button press), the output pin is toggled from LOW to HIGH or HIGH to LOW. There's a minimum delay between toggles to debounce the circuit (i.e. to ignore noise).

The circuit:

- LED attached from pin 13 to ground through 220 ohm resistor

- pushbutton attached from pin 2 to +5V

- 10 kilohm resistor attached from pin 2 to ground

- Note: On most Arduino boards, there is already an LED on the board connected to pin 13, so you don't need any extra components for this example.

```

Sensors and Communications protocols

Install Adafruit_Si7021 library

To begin reading sensor data, you will need to [install the Adafruit_Si7021 library's code on your Arduino IDE](#). It is available from the Arduino library manager to be downloaded using the IDE.

From the IDE, open up the library manager:

And type in `adafruit_si7021` to locate the library. Click install

Also install the `Adafruit Unified Sensor` library in the same way

[Arduino Code | Adafruit Si7021 Temperature & Humidity Sensor | Adafruit Learning System](#)
